

ACCURATE DATA ANNOTATOR

MASTER ANNOTATION STANDARDS & MANUAL

Resource Library Code: ADA-NLP-2026

Authoritative Quality Control Manual

Target System: Advanced NLP, LLM Fine-Tuning & Evaluation

Version A & B Bundle

PART I: VERSION A – ENGLISH ANNOTATION STANDARDS

1. INTRODUCTION TO ADA'S ANNOTATION STANDARDS

Welcome to the **Accurate Data Annotator (ADA)** master production pipeline. In the modern AI economy, high-quality labeled data represents the critical framework upon which reliable, ethical, and high-performing Large Language Models (LLMs) are constructed. Our "Human-in-the-Loop" philosophy centers on the absolute truth that context completely dominates generic keywords.

This document outlines the rigorous standards required across all text annotation workflows executed by ADA specialists. Precision, objective consistency, and deep comprehension are our baseline metrics. Every label applied informs production-grade models, requiring annotators to possess unmatched linguistic vigilance.

2. GENERAL ANNOTATOR RULES

All ADA production specialists must strictly adhere to the following baseline execution parameters:

- **Context Over Keywords:** Never apply a label based solely on isolated words. Analyze the complete sentence, paragraph, and user intent.
- **Objective Evaluation:** Eliminate personal, political, or cultural bias. Annotate according to structural criteria, not subjective feelings.
- **Edge Case Escalation:** If an item falls exactly between two classifications, consult the project-specific protocol or flag the item for Senior QC Review. Never guess randomly.
- **Formatting Continuity:** Ensure exact spacing and token selection when handling spans or entity boundaries. Inclusion of trailing spaces is strictly prohibited.

3. TEXT ANNOTATION GUIDELINES

Text annotation requires breaking down complex natural language structures into structured schema formats. ADA pipelines utilize specialized workflows categorized into distinct analytical domains. Below are the definitive protocols for Sentiment Analysis, Intent Classification, and Named Entity Recognition (NER).

3.1 SENTIMENT ANALYSIS

Sentiment analysis evaluates the emotional undertone and psychological stance expressed within a specific text fragment. Annotators must categorize text into one of three core polarities:

POLARITY	CORE DEFINITION	PRODUCTION EXAMPLE
POSITIVE	Expression of explicit satisfaction, praise, gratitude, or constructive approval.	"The latest interface update dramatically reduced our pipeline lag time. Stellar work!"
NEUTRAL	Objective statements of fact, queries lacking emotional content, or mixed but balanced views.	"The data processing batch scheduled for 04:00 UTC concluded within forty minutes."
NEGATIVE	Expression of explicit frustration, system errors, dissatisfaction, or critical disapproval.	"The system crashed completely during the validation phase and wiped our local state."

3.2 INTENT CLASSIFICATION

Intent Classification maps natural language strings onto exact operational tasks or system actions. It answers the fundamental question: *What is the end-user trying to accomplish?*

PRODUCTION MAPPING CLASSIFICATIONS

- **Informational:** Searching for data or conceptual clarity. (e.g., "What is the baseline learning rate?")
- **Transactional:** Seeking to modify records or initiate execution. (e.g., "Cancel my premium subscription immediately.")
- **Navigational:** Aiming to reach a specific digital location. (e.g., "Redirect me to the API tokens page.")

3.3 NAMED ENTITY RECOGNITION (NER)

NER requires identifying and highlighting rigid designators (entities) within unstructured text string sequences and mapping them to predefined target classes.

ENTITY TAG	SCOPE & IDENTIFICATION LIMITS	SAMPLE TOKEN STREAM LABELED
PER (Person)	First, middle, last names, and specific official pseudonyms. Excluding general titles.	"The project direction was shifted by [Batoul H. Hassaballa] yesterday."
ORG (Organization)	Corporations, academic institutions, non-profits, and official state units.	"All compliance protocols were audited by [Accurate Data Annotator] ."

ENTITY TAG	SCOPE & IDENTIFICATION LIMITS	SAMPLE TOKEN STREAM LABELED
LOC (Location)	Geographical territories, natural structures, political states, cities, and facilities.	"The offshore engineering infrastructure is positioned in [Egypt] ."

PART II: VERSION B – BILINGUAL EDITION

(ENGLISH / العربية)

CROSS-BORDER DATA STANDARDS / معايير البيانات عابرة الحدود

1. INTRODUCTION TO ADA STANDARDS Accurate Data Annotator (ADA) mandates absolute clarity across both localized linguistic systems. Language models require identical semantic weighting regardless of whether the source sequence is formatted in Western character systems or Arabic script.	1. مقدمة لمعايير منصة ADA تفرض منصة دقة مبرمجي البيانات (ADA) وضوحاً مطلقاً عبر كلا النظامين اللغويين المحليين. تتطلب نماذج اللغة وزناً دلاليّاً متطابقاً بغض النظر عما إذا كانت السلسلة المصدر منسقة بنظم الأحرف الغربية أو بالخط العربي.
2. GENERAL ANNOTATOR RULES Rule 1: Always prioritize structural intent over literal phrasing. Rule 2: Avoid dialectal conflation; separate Modern Standard Arabic (MSA) strict meanings from colloquial expressions.	2. القواعد العامة للمُدقّق القاعدة 1: إعطاء الأولوية دائماً للقصد البنيوي والسياق على الألفاظ الحرفية. القاعدة 2: تجنب خلط اللهجات؛ افصل بدقة بين معاني اللغة العربية الفصحى الحديثة والتعبيرات العامية.
3. SENTIMENT ANALYSIS MAPPING POSITIVE: "The system runs flawlessly." NEGATIVE: "The system failed entirely."	3. تصنيف تحليل المشاعر إيجابي: "النظام يعمل بلا أي عيوب." سلبي: "فشل النظام بشكل كامل وجذري."
4. INTENT CLASSIFICATION Intent: Transactional Example: "Process my payment details now."	4. تصنيف القصد والنية القصد: إجرائي / مالي مثال: "قم بمعالجة تفاصيل الدفع الخاصة بي الآن."

5. NAMED ENTITY RECOGNITION

Extracting **ORG** or **PER** across lexical contexts:

"Audit performed at **[ADA]** by **[Batoul]**."

5. تمييز الكيانات المسماة (NER)

استخراج **المؤسسات** أو **الأشخاص** عبر السياقات اللفظية:

"تم التدقيق في **[ADA]** بواسطة **[بتول]**."
